Centroid-based clustering is the one you probably hear about the most. It's a little sensitive to the initial parameters you give it, but it's fast and efficient. These types of algorithms separate data points based on multiple centroids in the data. Each data point is assigned to a cluster based on its squared distance from the centroid.

This is a method of determining the centroid of an L-shaped object. Divide the shape into two rectangles, as shown in fig 2. Find the centroids of these two rectangles by drawing the diagonals. Draw a line joining the centroids. The centroid of the shape must lie on this line AB. Divide the shape into two other rectangles, as shown in fig 3.

Using Weighted K-Means Clustering to Determine ...

k-means clustering is a method of vector quantization, originally from signal processing, that aims to partition n observations into k clusters in which each observation belongs to the cluster with the nearest mean (cluster centers or cluster centroid), serving as a prototype of the cluster. This results in a partitioning of the data

space into Voronoi cells.

Since k-means clustering aims to converge on an optimal set of cluster centers

(centroids) and cluster membership based on distance from these centroids via successive iterations, it is intuitive that the more optimal the positioning of these initial centroids, the fewer iterations of the k-means clustering algorithms will be required for convergence.
