Embedded Systems **And Software** **Validation**

Modern embedded systems require high performance, low cost

and low power consumption. Such systems typically consist of a heterogeneous collection of processors, specialized memory subsystems, and partially programmable or fixed-function components. This heterogeneity, coupled with issues such as hardware/software partitioning, mapping, scheduling, etc., leads to a large number of design possibilities, making performance debugging and validation of such systems a difficult problem.

process, weaving it into the design process itself. The focus of our book is on validation, but from an embedded software and systems perspective. The methods we have covered (testing/model-checking)

It is this, high

dependency on hardware, which makes testing, verification, and validation of embedded Softwares far more demanding than of general software. Moreover, several safety-critical embedded systems are also strictly real-time, or at least soft real-time, which requires timing properties to be verified in tandem with functional properties.

This type of validation is especially useful for the software components consisting of a combination of generated code and handwritten code that need to be integrated and executed on the embedded target platform. The SIL tests
