When two atoms join together in a covalent bond, they form a molecule that shares electrons. Unlike in the ionic bond, neither of the atoms in a covalent bond loses or gains an electron; instead, both atoms use a pair of shared electrons. The simplest covalent bonds form between atoms of the same element. To help predict which atoms are likely to form covalent bonds, scientists use the octet rule.

The first is called a non-polar covalent bond. This is where the atoms equally attract and share the electrons. An example of this is two hydrogen atoms ($\text{H}-\text{H}$) sharing a pair of electrons. Each hydrogen nucleus has one proton that equally "tugs" or attracts the bonding pair of electrons. The second type of covalent bond is the polar covalent bond. This is where the two atoms in the covalent bond are not the same and the attraction to the electron pair is not equal.
