General description. New procedures for characterizing recombinant DNA-derived proteins by peptide mapping are presented. Among these are capillary electrophoresis, analysis of glycopeptides, and the use of electrospray and matrix-assisted laser desorption mass spectrometry. Practical procedures for sample preparation, enzyme digestion, separation, and structural analysis of the separated species are also provided.

Peptide mapping for protein identification using mass spectrometry (MS). In the first step, the protein is proteolytically digested (usually with trypsin) and the experimental masses of the peptides are measured using MS. The sequences of the proteins within the selected database are digested in silico based on the specificity of the enzyme used. The masses of these

peptides are calculated and theoretical mass spectra are constructed.

Biopharmaceutical peptide mapping. Peptide mapping is a critical workflow in biotherapeutic protein characterization and is essential for elucidating the primary amino acid structure of proteins. For recombinant protein pharmaceuticals, such as monoclonal antibodies (mAbs) and antibody-drug conjugates (ADCs), peptide mapping is used for proof of identity, primary structural characterization and quality assurance/quality control (QA/QC).

The chemical origin of life is full of chicken-and-egg conundrums. Among these is the origin of protein synthesis. Nature's protein-based enzyme catalysts are built from the polymerization of amino acids, yet this process itself requires enzymes, adenosine triphosphate (ATP), and, most often, a ribosome. How were the first proteins formed on the path from chemistry to life?
