Aldehydes and ketones undergo a variety of reactions that lead to many different products. The most common reactions are nucleophilic addition reactions, which lead to the formation of alcohols, alkenes, diols, cyanohydrins ($\text{RCH}(\text{OH})\text{C}\equiv\text{N}$), and imines ($\text{R}_2\text{C}=\text{NR}$), to mention a few representative examples.

How will you distinguish between aldehyde and ketone?

Among the most useful and characteristic reactions of aldehydes and ketones is their reactivity toward strongly nucleophilic (and basic) metallo-hydride, alkyl and aryl reagents. If the carbonyl functional group is converted to an acetal these powerful reagents have no effect; thus, acetals are excellent protective groups, when these irreversible addition reactions must be prevented.

Reactions Of Aldehydes Ketones Chemsheets

Aldehydes and ketones can be converted into 1°, 2° and 3° amines using reductive amination. The reaction takes place in two parts. The first step is the nucleophilic addition of the carbonyl group to form an imine. The second step is the reduction of the imine to an amine using a reducing agent. The most common reaction of aldehydes and ketones is nucleophilic addition. This is usually the addition of a nucleophile and a proton across the C=O double bond. As the nucleophile attacks the carbonyl group, the carbon atom changes from sp² to sp³. The electrons of the C=O bond are pushed out onto the oxygen, generating an alkoxide anion.

Ozonolysis is a reaction method in which addition of ozone molecules or O₃ to an

alkene compound leads to the formation of ozonide. Reduction of the ozonide compound with the help of zinc dust and water produces the smaller molecules, which in this case will be the respective aldehydes and ketones.

Aldehydes contain their carbonyl group at the end of the carbon chain and are susceptible to oxidation while Ketones contain theirs in the middle of the carbon chain and are resistant to oxidation. Jones's Test, Tollen's Reagent and Iodoform Reaction were the three tests used to determine the

reactions of aldehydes and ketones. The Chromic Anhydride test caused Aldehydes to turn blue, and Ketones orange.
