Roller Support and Reactions and Applications in a Structure Roller supports only resists perpendicular forces and they cannot resist parallel or horizontal forces and moment. It means, the roller support will move freely along the surface without resisting horizontal force. This type of support is provided at one end of bridge spans.

Roller supports are free to rotate and translate along the surface upon which the roller rests. The surface can be horizontal, vertical, or sloped at any angle. The resulting reaction force is

always a single force that is perpendicular to, and away from, the surface. Roller supports are commonly located at one end of long bridges.

The fact that the shear force is a polynomial (curve) between E and F also tells us the bending moment's slope is continuously changing, i.e. it's also a curve. But the fact that the shear force changes sign at B, means the bending moment diagram has a peak at that point.

The larger velocity the coaster has, the larger is the interaction force between the rails and the coaster, consequently the coaster will be more tightly attached to the rails and will not fall down. On the contrary, if the velocity is smaller, the

rails will give smaller or even no reaction force, and the roller coaster will risk falling down.

At most, there'll be a slight force due to
the friction of the rollers on the ground,
but that's usually assumed to be zero.
Once you get into a dynamic system
under a constant force (and therefore
constant acceleration), then sure, you
might get some internal inertial forces,
but I don't think that's what you're
asking about.
