Servo Motor Tuning - Rocket Science or Walk In the Park?

Tuning a servo system is a complex and iterative process. It typically requires tuning multiple control loops, each with its own gains (proportional, integral, and/or derivative) to be adjusted. In addition, tuning a servo drive usually requires adjustments to additional parameters including acceleration and velocity feed-forward gains and filters to reduce oscillations .

Scales introduce several variables into servo tuning. The motor encoder is used to control the velocity loop and the scale is used to control the positioning loop. There is always a lag between the motor encoder feedback and the scale feedback. That lag needs to be accounted for in the tuning.

Fanuc servo tuning - Practical Machinist

Servo tuning is a method of adjusting the feedback to determine how hard the system tries to correct the error. The process of servo tuning means tweaking the various gains and motion parameters in the servo controller so that performance is optimized—i.e. the motion is smooth, with little or no audible noise during and after the motion, and with little or no position error after the commanded motion is completed.

FAQ: How are the controls for servo motors tuned?
