For part 1, the freezing point of deionized water was determined. An ice bath was prepared by filling a 600mL beaker $\frac{3}{4}$ full of ice and covered with $\frac{1}{4}$ to $\frac{1}{2}$ inches of rock salt. The ice-salt mixture was stirred with a stirring rod and the mercury thermometer was used to assure that the temperature dropped to $-50\text{ }^{\circ}\text{C}$ or below.

The determination of the freezing and melting points involves four distinct steps.

These are; calibration, loading, deep freezing, and determination. By determining the solution's freezing point, it is possible to establish the number of particles in it, an aspect that allows the determination of its concentration.

The freezing point of water to which antifreeze has been added is lower than that of pure water. The freezing point of vodka is lower than that of pure water. Vodka and other high-proof alcoholic beverages typically don't freeze in a home freezer. Yet, the freezing point is higher than that of pure ethanol (-173.5°F or -114.1°C).

What Freezing Point Depression Is and How It Works

If the solution is treated as an ideal solution, the extent of

freezing-point depression depends only on the solute concentration that can be estimated by a simple linear relationship with the cryoscopic constant ("Blagden's Law"): $\Delta T_F = K_F \cdot b \cdot i$, where: ΔT_F , the freezing-point depression, is defined as $T_F(\text{pure solvent}) - T_F(\text{solution})$.

B. Freezing point determination of a solution of HAc and an unknown solute. 1. Add 1.5 mL of the unknown solute to the test tube containing the HAc sample that you used determined the freezing point of pure HAc in experiment A. Stir well. We will call this solution "solution #1". 2. Insert the

temperature probe. 3. Repeat steps 4-8. 4.

Experiment 9: Freezing point depression

Freezing point and boiling point of a solution differ from those of the pure solvent by amounts that are directly proportional to the molal concentration of the solute and can be expressed with the equation below: $\Delta T = K \cdot m$ where ΔT is the freezing-point lowering or boiling-point elevation, K is molal freezing (or boiling) constant which is specific for each solvent, m is the molality of the solution (number of moles of solute /kg of solvent).

Determination of the Freezing Point

Depression.docx ...

Determination of Molar Mass by Freezing-Point Depression When a solute is dissolved in a solvent, the freezing temperature is lowered in proportion to the number of moles of solute added. This property, known as freezing-point depression, is a colligative property; that is, it depends on the ratio of solute and solvent particles, not on the nature of the substance itself.
