Ethylene Glycol Production From Syngas

In the process described here, ethylene glycol is produced from synthesis gas (syngas), a gaseous mixture of carbon monoxide (CO) and hydrogen (H₂). CO is first converted to dimethyl oxalate (DMO), which is then hydrogenated to form ethylene glycol (Figure 1). Carbonylation. The CO and H₂ in the feed syngas are separated. The recovered CO is fed to the carbonylation reactors along with a recycled stream from the nitrite

regeneration section (discussed below) that contains an intermediate ...

Published January 1985. This review examines the technology for producing ethylene glycol directly from syngas (mixtures of hydrogen with carbon monoxide). Research efforts have focused on

a high-pressure, liquid-phase process that uses a homogeneous catalyst and a high-dielectric solvent. The catalyst complex is based on rhodium or ruthenium, generally with a ligand and a nitrogen-containing Lewis base, and often with another modifier.

Published October 2012. This review presents a technoeconomic evaluation of a newly commercialized monoethylene glycol (MEG) production route, which, if it successfully meets the desired level of product purity and catalyst stability, could revolutionize the MEG industry with the possibilities of switching its production from the current ethylene-based source to a new coal-based source.

Ethylene glycol production and purification. Ethylene oxide is reacted with CO₂, forming ethylene

carbonate, which is then hydrolyzed to form MEG and CO₂. Both reactions are carried out in the liquid phase using homogeneous catalysts. CO₂ streams from the reaction steps are recycled to the ethylene carbonate reactor. MEG is purified in two distillation columns where water is removed, leading to the final MEG product.

It consists of the reaction of the ethylene oxide with water to form Monoethylene Glycol (MEG). $\text{H}_2\text{C O CH}_2 + \text{H}_2\text{O} \rightarrow \text{H}_2\text{C CH}_2\text{OH} + 91.0 \text{ kJ}$ The above reaction is followed by the reaction of the

MEG with the remaining Ethylene Oxide to form higher derivatives of the glycol.

A Paper On Manufacturing Of Ethylene Glycol

There are two main routes for Ethylene Glycol (Monoethylene Glycol/MEG) production: one is the Olefin/EO (Ethylene Oxide) Route starting from either naphtha, ethane or methanol, the licensors include Shell, SD, UCC and etc. And the other is the DMO (dimethyl oxalate) Route newly emerged in China these years, starting from syngas.
