Widrow's Least Mean Square (LMS) Algorithm

Least mean squares algorithms are a class of adaptive filter used to mimic a desired filter by finding the filter coefficients that relate to producing the least mean square of the error signal. It is a stochastic gradient descent method in that the filter is only adapted based on the error at the current time. It was invented in 1960 by Stanford University professor Bernard Widrow and his first Ph.D. student, Ted Hoff.

In mathematics, a square root of a number x is a number y such that $y^2 = x$; in other words, a number y whose square (the result of multiplying the number by itself, or $y \cdot y$) is x . For example, 4 and -4 are square roots of 16, because $4^2 = (-4)^2 = 16$.

In signal processing applications, the most popular method for adapting the weights is the simple LMS (least mean square) algorithm (Widrow and Hoff, 1960), often called the Widrow-Hoff Delta Rule (Rumelhart et al., 1986). This algorithm minimizes the sum of squares of the linear errors over the training set.

Perceptrons, Adalines, and Backpropagation

In the field of electrical engineering and signal processing, few algorithms have proven as adaptable as the least-mean-square (LMS) algorithm. Devised by Bernard Widrow and M. Hoff, this simple yet effective algorithm now represents the cornerstone for the design of adaptive transversal (tapped-delay-line) filters.

An adaptive filter is a system with a linear filter that has a transfer function controlled by variable parameters and a means to adjust those parameters according to an optimization algorithm. Because of the complexity of the optimization

algorithms, almost all adaptive filters are digital filters. Adaptive filters are required for some applications because some parameters of the desired ...
