OFDM is used in the downstream and is a common channel shared by all compatible cable modems. OFDMA is used in the upstream by cable modems transmitting data to the CMTS. OFDMA is a time- and frequency-shared medium, meaning the CMTS schedules time and frequency slots to the modems allowing the modems to time share the same frequency and transmit their data on OFDMA subcarriers on the upstream.

DOCSIS 3.1 uses a new physical layer based upon Orthogonal Frequency Division Multiplexing (OFDM) and an error correction scheme called Low Density Parity Check (LDPC). The data path consists of one or more OFDM channels. Each OFDM channel has a PHY link channel (PLC) for initializing cable modems (CMs).

When you do notice that a DOCSIS 3.1 orthogonal frequency division multiplexing (OFDM) channel or cable modem is having impairments, DOCSIS 3.1 provides the capabilities to quickly retrieve all subcarrier MER values directly from the cable modem. This lets you find an impairment anywhere in the OFDM haystack and is a powerful feature of DOCSIS 3.1.

First, the RPD staggers OFDM blocks and after the amplifier stages and filters the output of the RPD node is sloped up to 1.2 GHz. While every OFDM block has the same slope, their signal level is reduced. Due to the tilt of coaxial cables, the Cable Modem sees a flat level until 1.2 GHz and the staggered OFDM blocks up to 1.8 GHz.
