To disperse two immiscible liquids, one needs a third component, namely, the emulsifier. The choice of the emulsifier is crucial in the formation of the emulsion and its long-term stability [1-3]. Emulsions may be classified according to the nature of the emulsifier or the structure of the system. This is illustrated in Table 1.1.

Emulsion Stability The process by which an emulsion coalesces (completely breaks i.e., the system separates into bulk oil and water phases), is generally considered to be governed by four different droplet loss mechanisms: Brownian locculation, creaming, sedimentation locculation, and disproportionation, shown schematically in Figure 1. The first three

are the primary methods by which emulsions are destabilized, though all

the field of colloids and interfacial science. Surfactants and colloidal particles are often used to stabilize emulsions. Surfactants are amphiphilic molecules; they minimize the energy required for the emulsion formation by reducing oil-water interfacial tension.

The stability of Pickering emulsions can also be enhanced by the formation of a three-dimensional viscoelastic network of colloidal particles in the continuous phase. This stabilization mechanism relies on their being a sufficiently high concentration of non-adsorbed protein particles in the continuous phase, as

variety of emulsion systems. It discusses spontaneous emulsification and the formation of "nanoemulsions" as well as droplet-droplet interactions in different

electrical fields (electrocoalescence), and the formulation, composition, and preparation variables that contribute to the inversion in emulsion systems.
