Contourites, formed by oceanic currents which circulate along the continental slope, are often altered by "turbiditic" sedimentary events. These turbiditic deposits are formed by gravitational processes at the seabed sharpest slopes, transverse to the continental slope.

**Contourites - AAPG
Wiki**

A contourite is a sedimentary deposit commonly formed on continental rise to lower slope settings, although they may occur anywhere that is below storm wave base. Countourites are produced by thermohaline-induced deepwater bottom currents and may be influenced by wind or tidal forces. The geomorphology of contourite deposits is mainly influenced by the deepwater bottom-current velocity, sediment supply, and seafloor topography.

This type of contourite

deposit is related to
deep channels,
passageways or
gateways through
which the bottom
circulation is
constrained so that
flow velocities are

(e.g., Vema Channel,

Gateways are very
important narrow
conduits that cut
across the sills
between ocean basins
and thereby allow the
exchange of deep and
intermediate water
masses.

Contourite drifts were first described in the North Atlantic Ocean, where they were called "outer ridges" or "sediment drifts" (e.g., McCave and Tucholke, 1986). Present at most of modern continental margins, they are as frequent as deep-sea turbidite systems, occurring anywhere from the abyssal

seafloor to slope settings.
